(57) **ABSTRACT**

A transmission apparatus for a wireless device, comprising: an antenna for receiving an original signal and for backscattering a modulated signal containing information from the wireless device; a variable impedance coupled to the antenna, the variable impedance having an impedance value; a delta-sigma modulator coupled to the variable impedance for modulating the impedance value, and thereby a backscattering coefficient for the antenna, in accordance with the information to generate the modulated signal; and, a decoder coupled to the delta-sigma modulator for generating the impedance value from the information.

TRANSMISSION APPARATUS FOR A WIRELESS DEVICE USING DELTA-SIGMA MODULATION

This application is a continuation-in-part of U.S. patent application Ser. No. 13/874,996, filed May 1, 2013, and incorporated herein by reference, and claims priority from U.S. Provisional Patent Application No. 61/670,259, filed Jul. 11, 2012, and incorporated herein by reference.

FIELD OF THE INVENTION

This invention relates to the field of radio frequency identification systems, and more specifically, to transmission apparatus for wireless devices (e.g., tags) in backscattered and inductively coupled radio frequency identification systems.

BACKGROUND OF THE INVENTION

Radio frequency identification ("RFID") systems have become very popular in a great number of applications. A typical RFID system **100** is shown in FIG. 1. The RFID system **100** includes an application system **110**, a reader **120**, and a tag **130**. When the tag **130** appears in the operational range of the reader **120**, it starts receiving both energy **140** and data **150** via its antenna **133** from the reader **120** via its transmitter/receiver **121** and antenna **123**. A rectify circuit **131** in the tag **130** collects and stores the energy **140** for powering the other circuits (e.g., control/modulator **132**) in the tag **130**. After collecting enough energy **140**, the tag **130** may operate and send back pre-stored data to the reader **120**. The reader **120** then passes the received response data via a communications interface **160** to the server system/database **111** of the application system **110** for system applications.

The tags **130** in RFID system **100** may be classified into passive and active types according to the power provisions of the tags. Passive tags do not have their own power supply and therefore draw all power required from the reader **120** by electromagnetic energy received via the tag's antenna **133**. In contrast, active tags incorporate a battery which supplies all or part of the power required for their operation.

A typical transmission method of energy **140** and data **150** between a reader **120** and a tag **130** in a RFID system **100** is by way of backscatter coupling (or backscattering). The antenna **123** of the reader **120** couples energy **140** to the tag **130**. By modulating the reflection coefficient of the tag's antenna **133**, data **150** may be transmitted between the tag **130** and the reader **120**. Backscattering, as shown in FIG. 2, is typically used in microwave band RFID systems. Power P_{in} is emitted from the reader's antenna **123**. A small proportion of P_{in} is received by the tag's antenna **133** and is rectified to charge the storing capacitor in the tag **130** for serving as a power supply. After gathering enough energy, the tag **130** begins operating. A portion of the incoming power P_{in} is reflected by the tag's antenna **133** and returned as power P_{return} . The reflection characteristics may be influenced by altering the load connected to the antenna **133**. In order to transmit data **150** from the tag **130** to the reader **120**, a transistor is switched on and off in time with the transmitted data stream. The magnitude of the reflected power P_{return} may thus be modulated and picked up by the reader's antenna **123**.

Amplitude shift keying ("ASK") modulation is typically used in RFID systems **100**. In ASK modulation, the amplitude of the carrier is switched between two states controlled by the binary transmitting code sequence. Also, in some applications, phase shift keying ("PSK") modulation is also used.

2

However, arbitrary complex type modulations are generally not used in current RFID backscattering systems. Here complex type modulations are ones that are normally expressed as $I+jQ$, where I is the in-phase component, Q is the quadrature component, and j is the square root of -1 .

For reference, the beginnings of RFID use may be found as far back as World War II. See for example, Stockman H., "Communication By Means of Reflected Power," Proc. IRE, pp. 1196-1204, October 1948. Passive and semi-passive RFID tags were used to communicate with the reader by radio frequency ("RF") backscattering. In backscattering RFID systems, a number of tags **130** interact with a main reader device **120** as shown in FIG. 3. The reader **130** is used to: (i) power up the tags **130** via the power of the RF signal; (ii) transfer data to the tags **130**; and, (iii) read information from the tags **130**.

Typically, a link budget exists between the reader **120** and the tag **130**. The tag **130** communicates with the reader **120** by backscattering the RF signal back to the reader **120** using either ASK or PSK modulation. One advantage of the backscattering method is that it does not need to generate an RF carrier on chip within the tag **130**, thus it requires less power, less complexity, and less cost. A typical block diagram of a backscattering transmission apparatus **400** for a tag **130** is shown in FIG. 4. In FIG. 4, Z_{ant} is the impedance of the antenna **133** and Z_o is a fixed impedance which is in parallel with a switch **410**. The reflection coefficient Γ is given by the equation:

$$\Gamma = \frac{Z_o - Z_{ant}}{Z_o + Z_{ant}}$$

With the switch **410** on (i.e., closed), $\Gamma=1$. When the switch is off (i.e., open), $\Gamma=0$. By turning the switch **410** on and off, an ASK signal **420** is generated as shown in FIG. 4.

PSK signals may also be generated using a similar set up. This is shown in the transmission apparatus **500** illustrated in FIG. 5. Here, the reflection coefficient Γ is given by the equation:

$$\Gamma = \frac{(Z_i + Z_o) - Z_{ant}}{(Z_i + Z_o) + Z_{ant}}$$

Here, Z_i is an impedance that is switched in as per FIG. 5. So, depending on the position of the switch **410**, **510**, backscattering is designed to produce either an ASK signal **420** or a PSK signal **520**.

As shown in FIG. 6, using backscattering techniques, each tag **130** sends RF signals **610** on the same carrier **620** and hence overlapping the RF spectrum of other tags **130**. This poses a challenge which respect to avoiding data collisions between all of the tags **130**. In current systems, these collision issues are solved via the communication protocol used between the reader **120** and the tags **130**.

In Thomas S., Reynolds S. Matthew, "QAM Backscatter for Passive UHF RFID Tags", IEEE RFID, p. 210, 2010 (Thomas et al.), the generation of four quadrature amplitude modulation ("QAM") signals was proposed in which a number of Γ values are switched in and out.

There are several problems with prior tag transmission apparatus. For example, systems such as that proposed by Thomas et al. are limited in the nature of signals that they can backscatter. That is, any arbitrary signal cannot be transmitted. For example, if the QAM signal is first filtered via a filter,

Thomas et al.'s system cannot transmit a filtered version of the QAM signal. As another example, if the signal is simply a sine wave or a Gaussian minimum shift keying ("GMSK") signal, Thomas et al.'s system cannot be used to transmit this signal. As a further example, Thomas et al.'s system cannot transmit single side band signals.

A need therefore exists for an improved transmission apparatus for wireless devices (e.g., tags) in backscattered and inductively coupled radio frequency identification systems. Accordingly, a solution that addresses, at least in part, the above and other shortcomings is desired.

SUMMARY OF THE INVENTION

According to one aspect of the invention, there is provided a transmission apparatus for a wireless device, comprising: an antenna for receiving an original signal and for backscattering a modulated signal containing information from the wireless device; a variable impedance coupled to the antenna, the variable impedance having an impedance value; a delta-sigma modulator coupled to the variable impedance for modulating the impedance value, and thereby a backscattering coefficient for the antenna, in accordance with the information to generate the modulated signal; and, a decoder coupled to the delta-sigma modulator for generating the impedance value from the information.

BRIEF DESCRIPTION OF THE DRAWINGS

Features and advantages of the embodiments of the present invention will become apparent from the following detailed description, taken in combination with the appended drawings, in which:

FIG. 1 is a block diagram illustrating a radio frequency identification (RFID) system in accordance with the prior art;

FIG. 2 is a block diagram illustrating transmission of energy and data between a reader and a tag in a RFID system in accordance with the prior art;

FIG. 3 is a block diagram illustrating communications between a reader and multiple tags in an RFID system in accordance with the prior art;

FIG. 4 is a block diagram illustrating a transmission apparatus for a tag for backscattering ASK and/or on-off keying ("OOK") signals in accordance with the prior art;

FIG. 5 is a block diagram illustrating a transmission apparatus for a tag for backscattering PSK signals in accordance with the prior art;

FIG. 6 is a block diagram illustrating multiple tags communicating back to a reader using the same frequency spectrum in accordance with the prior art;

FIG. 7A is a block diagram illustrating a transmission apparatus for a wireless device for backscattering signals to a reader based on a digital wave form input in accordance with an embodiment of the invention;

FIG. 7B is a block diagram illustrating a variable impedance circuit for the transmission apparatus of FIG. 7A in accordance with an embodiment of the invention;

FIG. 8 is a graph illustrating the relationship between Gamma (Γ) and Z_i in accordance with an embodiment of the invention;

FIG. 9 is a block diagram illustrating a transmission apparatus with an adder for a wireless device for backscattering arbitrary modulated signals to a reader based on I and Q data input in accordance with an embodiment of the invention;

FIG. 10A is a block diagram illustrating inductive coupling between a reader and a wireless device in a RFID system in accordance with an embodiment of the invention;

FIG. 10B is a block diagram illustrating an equivalent circuit for the RFID system of FIG. 10A in accordance with an embodiment of the invention; and,

FIG. 11 is a block diagram illustrating a transmission apparatus using inductive coupling for a wireless device for transmitting signals to a reader based on a digital waveform input in accordance with an embodiment of the invention.

It will be noted that throughout the appended drawings, like features are identified by like reference numerals.

DETAILED DESCRIPTION OF THE EMBODIMENTS

In the following description, details are set forth to provide an understanding of the invention. In some instances, certain software, circuits, structures and methods have not been described or shown in detail in order not to obscure the invention. The term "apparatus" is used herein to refer to any machine for processing data, including the systems, devices, and network arrangements described herein. The term "wireless device" is used herein to refer to RFID tags, RFID transponders, cellular telephones, smart phones, portable computers, notebook computers, or similar devices. The present invention may be implemented in any computer programming language provided that the operating system of the data processing system provides the facilities that may support the requirements of the present invention. Any limitations presented would be a result of a particular type of operating system or computer programming language and would not be a limitation of the present invention. The present invention may also be implemented in hardware or in a combination of hardware and software.

FIG. 7A is a block diagram illustrating a transmission apparatus **800** for a wireless device **130** for backscattering signals to a reader **120** based on a digital wave form input **830** in accordance with an embodiment of the invention. And, FIG. 7B is a block diagram illustrating a variable impedance **810** circuit for the transmission apparatus **800** of FIG. 7A in accordance with an embodiment of the invention. The present invention provides a method and apparatus for generating complex waveforms for passive and semi-passive RFID systems **100**. The complex wave forms may generate any type of complex modulation signals such as 8-constellation phase shift keying ("8PSK"), orthogonal frequency-division multiplexing ("OFDM"), or n-constellation quadrature amplitude modulation ("nQAM"). The method and apparatus may also be used to generate frequency channels for each wireless device **130**. According to one embodiment, the transmission apparatus (e.g., **800**) includes an antenna **133** coupled to a variable impedance **810** having an array of impedances (e.g., the first impedance Z_1 and the second impedance Z_2 in FIG. 7B) that are switched on or off (via the first switch S_1 and the second switch S_2 in FIG. 7B, respectively) via a backscattering decoder **820** and a delta-sigma ($\Delta\Sigma$) modulator **840** in the wireless device **130**. The signal **830** applied to the input of the decoder **820** may consist of any type of digital signal. The transmission apparatus **800** may include a processor **880** for controlling the decoder **820**, delta-sigma ($\Delta\Sigma$) modulator **840**, and variable impedance **810**, memory **890** for storing information (e.g., digital waveforms **830**), and related hardware and software as is known to one of skill in the art.

FIG. 8 is a graph illustrating the relationship between Gamma (Γ) and Z_i in accordance with an embodiment of the invention. Here, Γ is the reflection coefficient and Z_i is the impedance seen by the antenna **133**. The reflection coefficient is directly proportional to the digital wave form **830**. Accord-

5

ing to one embodiment of the invention, for backscattering RF applications, the reflection or backscattering coefficient Gamma (Γ) is given by:

$$\Gamma_i = \alpha e^{j\phi_i}$$

where ϕ_i is the phase, α is the magnitude of the reflection coefficient, and j is the square root of -1 . The back scattering impedance (i.e., the impedance seen by the antenna 133) is then given by:

$$Z_i = \frac{Z_a(1 + \alpha e^{j\phi_i})}{(1 - \alpha e^{j\phi_i})}$$

where Z_a is a constant (typically 50 ohms) and Z_i is the back scattering impedance value.

Assuming the phase is zero:

$$Z_i = \frac{Z_a(1 + \alpha)}{(1 - \alpha)}$$

If $s(t)$ is a signal (e.g., a sine wave) that is to be sent to the reader 120, it must be directly related to $\alpha(t)$ (e.g., $s(t)$ is directly proportional to $\alpha(t)$) and thus Γ . This produces an impedance value Z_i that varies with time.

In this embodiment, the signal $s(t)$ would be backscattered back to the reader 120 by the wireless device 130. In the transmission apparatus 800 shown in FIG. 7A, N-bits 821 are applied to the variable impedance 810 via the delta-sigma ($\Delta\Sigma$) modulator 840 such that the impedance value Z_i is encoded as shown in FIG. 8. Here, the variable impedance 810 has N states. If there are any errors in the encoding or imperfections in encoding of Z_i , these may be corrected within the reader 120. This is possible if for some time the signal $s(t)$ is known by the reader 120. The reader 120 then may add distortion to the incoming signal to correct for these imperfections.

Referring again to FIGS. 7A and 7B, the digital wave form information 830 (e.g., N-bit information) is applied to an element such as a decoder 820 that converts a scatter value or reflection coefficient Γ for the information 830 into an impedance value Z_i . This impedance value Z_i (e.g., N-bits 821) is then applied to a delta-sigma ($\Delta\Sigma$) modulator 840 which controls the switches S_1, S_2 in the variable impedance 810 to switch between respective impedances Z_1, Z_2 based on the output of the delta-sigma ($\Delta\Sigma$) modulator 840. For example, if the output of the delta-sigma ($\Delta\Sigma$) modulator 840 is "1", the impedance value Z_i is set to the value of the second impedance Z_2 . If the output of the delta-sigma ($\Delta\Sigma$) modulator 840 is "0", the impedance value Z_i is set to the value of the first impedance Z_1 . For example, impedance values of 116 ohms for the second impedance Z_2 and 21 ohms for the first impedance Z_1 may correspond to reflection coefficients Γ of 0.4 and -0.4 , respectively. If the desired reflection coefficient Γ is zero, the decoder 820 may determine an impedance value Z_i of 50 ohms (as per the graph shown in FIG. 8). The delta-sigma ($\Delta\Sigma$) modulator 840 now generates an output that produces an average impedance value for the variable impedance 810 of 50 ohms by switching between the 21 and 116 ohms impedances Z_2, Z_1 .

As shown in FIG. 7B, the variable impedance 810 circuit may be made up of an array of impedances Z_1, Z_2 that are switched in and out by respective switches S_1, S_2 depending on the digital decoder 820 and delta-sigma ($\Delta\Sigma$) modulator 840. Also, the variable impedance 810 may be controlled via

6

an analog signal, that is, after the Gamma to Z_i decoder 820 and delta-sigma ($\Delta\Sigma$) modulator 840, a digital to analog converter ("DAC") (not shown) may be added to drive the variable impedance 810.

The delta-sigma ($\Delta\Sigma$) modulator 840 may be of variable design. For example, according to one embodiment, the delta-sigma ($\Delta\Sigma$) modulator 840 may include or be a low-pass delta-sigma ($\Delta\Sigma$) modulator. According to another embodiment, the delta-sigma ($\Delta\Sigma$) modulator 840 may include or be a band-pass delta-sigma ($\Delta\Sigma$) modulator. According to one embodiment, the the delta-sigma ($\Delta\Sigma$) modulator 840 may be a single bit delta-sigma ($\Delta\Sigma$) modulator.

The delta-sigma ($\Delta\Sigma$) modulator 840 generates an output bit stream that represents the input data 821 from a DC level to some predetermined design bandwidth. Beyond the predetermined design bandwidth, quantized noise of the delta-sigma ($\Delta\Sigma$) modulator 840 may increase until, at some design cutoff point, the signal may be deemed to have too much quantization noise. According to one embodiment, one or more filters may be included in the variable impedance 810 circuit to filter out-of-band noise output from the delta-sigma ($\Delta\Sigma$) modulator 840. The variable impedance 810 circuit has an output electrically connected to the antenna 133. The delta-sigma ($\Delta\Sigma$) modulator 840 is coupled to an input to the variable impedance 810 circuit to digitally control the output of the variable impedance 810 circuit such that the reflection coefficient Γ of the antenna 133 may be adjusted by changing the impedance value Z_i of the variable impedance 810 circuit. According to one embodiment, the output of the delta-sigma ($\Delta\Sigma$) modulator 840 switches the impedance value Z_i of the variable impedance 810 between at least two states or impedance values Z_i .

According to one embodiment, the delta-sigma ($\Delta\Sigma$) modulator 840 may be of any order based on the bandwidth of the signals being applied to it. In addition, the clock applied to the delta-sigma ($\Delta\Sigma$) modulator 840 may set the over-sampling rate.

FIG. 9 is a block diagram illustrating a transmission apparatus 1000 with an adder 1050 for a wireless device 130 for backscattering arbitrary modulated signals to a reader 120 based on I and Q data input 1030 in accordance with an embodiment of the invention. According to one embodiment, the digital waveform 830 may be in-phase ("I") and quadrature ("Q") data 1030 as shown in FIG. 9. In FIG. 9, a digital signal generator ("DSS") 1040 may optionally up-convert (or offset) the I and Q data 1030. For example, the DSS 1040 may provide sine (or cosine) and cosine (or sine) signals 1070 that are applied to I and Q data by respective mixers 1071. Alternatively, the DSS 1040 may generate a constant value that is multiplied onto the I and Q data (i.e., the mixers 1071 act as gain elements). The Gamma to Z_i decoder 1020 receives the up-converted (or offset) I and Q data and applies it to the variable impedance 1010 via the delta-sigma ($\Delta\Sigma$) modulator 1080. The variable impedance 1010 may be made up of an array of impedances that are switched in or out (e.g., a parallel array of impedances with respective switches).

Summarizing the above, and referring again to FIGS. 7A and 7B, according to one embodiment an antenna 133 is used to backscatter an incoming radio frequency signal coming from a reader 120. The antenna 133 is electrically coupled to an array of impedance devices Z_1, Z_2 connected to switches S_1, S_2 . The array of impedance devices (e.g., variable impedance 810) may be digitally controlled by a digital block (e.g., decoder 820) and a delta-sigma ($\Delta\Sigma$) modulator 840 that are driven by an arbitrary N-bit digital waveform (e.g., 830). The digital block 820 presents an output to the array of impedances 810 via the delta-sigma ($\Delta\Sigma$) modulator 840 that is related to the N-bit digital waveform 830. A change in the impedance value of the array of impedances 810 backscatters

the incoming radio frequency signal thus producing a direct up-converted version of the output of the digital waveform **830** with respect to the incoming radio frequency. The output of the digital block **820** and delta-sigma ($\Delta\Sigma$) modulator **840** switches the array of impedances **810** between various states, which changes the characteristics of the reflection coefficient Γ . The signal **830** applied to the digital block **820** may take the form of any complex modulation signal, for example, GMSK, nPSK, 8PSK, nQAM, OFDM, etc., and such signals may be offset from the incoming radio frequency signal by a frequency \pm/ω .

Referring again to FIG. 9, the input **1030** to the digital block **1020** may alternate between in-phase (i.e., I) and quadrature (i.e., Q) signals via a control signal, for example. Also, the array of impedances **1010** may switch between backscattering coefficients that are 90 degrees offset from each other depending on whether the data is I or Q data. For example, if the I signals would produce backscattering coefficients at theta degrees then the Q signals would produce backscattering coefficients that are theta+90 degrees. The control signal may be a clock signal. The signals **1070** applied to the I and Q signals **1030** by the DSS **1040** may take the form of a direct current ("DC") signal (i.e., no frequency offset) or of sine and cosine waves at a selected frequency (i.e., to give a frequency offset of ω). The I and Q signals applied to the digital block **1020** may be adjusted to compensate for any errors in the impedance array **1010**, the delta-sigma ($\Delta\Sigma$) modulator **1080**, or the digital block **1020**. The array of impedances **1010** may include some filtering characteristics to filter off some of the digital block's **1020** or delta-sigma ($\Delta\Sigma$) modulator's **1080** out-of-band noise. And, the reader **120** used to detect the backscattered signal from the wireless device **130** may compensate for any errors generated within the impedance array **1010**, the digital block **1020**, or the delta-sigma ($\Delta\Sigma$) modulator **1080**.

FIG. 10A is a block diagram illustrating inductive coupling between a reader **120** and a wireless device **130** in a RFID system **1300** in accordance with an embodiment of the invention. FIG. 10B is a block diagram illustrating an equivalent circuit **1310** for the RFID system **1300** of FIG. 10A in accordance with an embodiment of the invention. And, FIG. 11 is a block diagram illustrating a transmission apparatus **1400** using inductive coupling for a wireless device **130** for transmitting signals to a reader **120** based on a digital waveform input **1430** in accordance with an embodiment of the invention.

According to one embodiment, communication between the reader **120** and the wireless device **130** may occur by sensing inductive loading changes in the reader **120**. Here, the reader **120** communicates with the wireless device **120** via magnetic or inductive coupling. This is shown in FIGS. 10A and 10B. FIGS. 10A and 10B show the basic principle of an inductive coupled RFID system **1300**. For inductive coupled systems **1300**, the underlying coils are defined by their size. It is known that a coupling system of two coils **1320**, **1330** may be represented by an equivalent transformer. The connection between these two coils **1320**, **1330** is given by the magnetic field (B) and the underlying value to describe this connection is the mutual inductance (M) and/or the coupling factor (k).

The law of Biot and Savart is given by:

$$\vec{B} = \frac{\mu_0 i_1}{4\pi} \oint \frac{d\vec{s} \times \vec{x}}{|\vec{x}|^3}$$

This allows the calculation of the magnetic field at every point as a function of the current, i_1 , as well as the geometry. Here, μ_0 is the permeability, x is the distance, and S describes the integration-path along the coil. Furthermore, the mutual inductance and the coupling factor are given by:

$$M = \int_{A_2} \frac{B(i_1)}{i_1} dA_2$$

$$k = \frac{M}{\sqrt{L_1 L_2}}$$

In these equations, A_2 describes the area of the second coil and L_1 and L_2 are the inductances of the two coils **1320**, **1330**. The distance x between the reader-coil **1320** and transponder-coil **1330** also determines the coupling factor. The equivalent model for this coupling is shown in FIG. 10B. The impedance value Z_i as seen by the reader **120** is directly related to the admittances $Y1$ and $Y2$. The admittances $Y1$ and $Y2$ are either modulated via amplitude (e.g., ASK) or in phase (e.g., PSK). The admittances $Y1$ and $Y2$ may also be modulated using multi-phase PSK and multi-amplitude ASK.

General speaking, the signal received back by the reader **120** is a function of the impedance value changing in the wireless device **130**. Once this impedance value changes, the signal seen by the reader **120** is modified and the reader **120** can detect this.

As in the case of backscattering, as shown in FIG. 11, a variable impedance **1410** may be modified by a decoder **1420** via a delta-sigma ($\Delta\Sigma$) modulator **1440**. Here, L **1405** is the inductance on the wireless device side. As in the case of backscattering, the same methods described above may be used, for example, for: (i) generating I and Q signals; (ii) general mapping from decoding to what the reader sees; and, (iii) if a signal is known by the reader, pre-distorting the signal to produce a corrected signal.

Summarizing the above, and referring again to FIG. 11, according to one embodiment there is provided a transmission apparatus **1400** for modifying an incoming radio frequency (RF) signal comprising: an inductive element **1405**; an array of impedances **1410** controlled by switches and circuits having an output electrically coupled to the inductive element **1405**; and, at least one digital block **1420** coupled to the array of impedances **1410** via a delta-sigma ($\Delta\Sigma$) modulator **1440** for digitally controlling the impedance value Z_i of the array of impedances **1410**; wherein the incoming RF signal is modified as the coupled array of impedances **1410** of the inductive element **1405** is adjusted.

The output of the decoder **1420** and delta-sigma ($\Delta\Sigma$) modulator **1440** may switch the array of impedances **1410** between various states which modifies the incoming RF signal. The signal **1430** applied to the digital block **1420** may take the form of any complex modulation signal, for example, GMSK, nPSK, 8PSK, nQAM, OFDM, etc., and such signals may be offset from the incoming radio frequency signal by a frequency \pm/ω .

The input **1430** to the digital block **1420** may alternate between the in-phase (i.e., I) and quadrature (i.e., Q) signals via a control signal, for example. Also, the array of impedances **1410** may modify the incoming RF signal from 0 to 90 degrees offset depending on whether the data is I or Q data. For example, if the I signal would produce an impedance value at theta degrees then the Q signal would produce an impedance value that is theta+90 degrees. The control signal may be a clock signal. The signals (e.g., **1070**) applied to the

I and Q signals may take the form of a DC signal or of sine and cosine waves at a selected frequency. The I and Q signals applied to the digital block **1420** may be adjusted to compensate for any errors in the impedance array **1410** due to variations in the impedance value in the array. The array of impedances **1410** may have some filtering characteristics to filter off some of the DAC quantized out-of-band noise. And, the reader **120** used to detect the modulated signal may compensate for any errors generated within the impedance array **1410**, the digital block **1420**, or the delta-sigma ($\Delta\Sigma$) modulator **1440**.

Thus, according to one embodiment, there is provided a transmission apparatus **800** for a wireless device **130**, comprising: an antenna **133** for receiving an original signal and for backscattering a modulated signal containing information **830** from the wireless device **120**; a variable impedance **810** coupled to the antenna **133**, the variable impedance **810** having an impedance value Z_i ; a delta-sigma ($\Delta\Sigma$) modulator **840** coupled to the variable impedance **810** for modulating the impedance value Z_i , and thereby a backscattering coefficient Γ for the antenna **133**, in accordance with the information **830** to generate the modulated signal (e.g., an arbitrary modulated signal); and, a decoder **820** coupled to the delta-sigma modulator **840** for generating the impedance value Z_i from the information **830**.

In the above transmission apparatus **800**, the variable impedance **810** may be coupled in series with the antenna **133**. The wireless device **130** may be powered by energy **140** from the original signal. The variable impedance **810** may include an array of impedances and respective switches. The decoder **820** may include a backscattering coefficient Γ to impedance value Z_i decoder. The information **830** may be an N-bit digital waveform **830**. The N-bit digital waveform **830** may be applied to the decoder **820** and then to a delta-sigma ($\Delta\Sigma$) modulator **840** to produce a control signal **821** for the variable impedance **810** that is related to the N-bit digital waveform **830**. A change in the impedance value Z_i may backscatter the original signal to produce the modulated signal, the modulated signal being a frequency offset (e.g., up-converted) form of the N-bit digital waveform **830**. The control signal **821** for the variable impedance **810** may switch an array of impedances within the variable impedance **810** which may change characteristics of the backscattering coefficient Γ of the antenna **133**. The information **830** may be a complex modulation signal **1030**. The complex modulation signal **1030** may be offset in frequency from the original signal. The complex modulation signal **1030** may be one of a GMSK signal, a nPSK signal, a 8PSK signal, a nQAM signal, and an OFDM signal. The complex modulation signal **1030** may be represented by $I+jQ$, where I is an inphase component, Q is a quadrature component, and j is a square root of -1 . The complex modulation signal **1030** may alternate between an in-phase signal (I) and a quadrature signal (Q) via a control signal. The variable impedance **810**, **1010** may switch between backscattering coefficients that are 90 degrees offset from each other depending on whether the complex modulation signal **1030** is the in-phase signal (I) or the quadrature signal (Q). The control signal may be a clock signal. The transmission apparatus **800**, **1000** may further include a digital signal generator **1040**. The digital signal generator **1040** may apply a constant value signal to the in-phase signal (I) and the quadrature signal (Q). The digital signal generator **1040** may apply sine and cosine wave signals **1070** to the in-phase signal (I) and the quadrature signal (Q), respectively. The complex modulation signal **1030** may be a sum of an in-phase signal (I) and a quadrature signal (Q). The transmission apparatus **800**, **1000** may further include a digital signal

generator **1040**. The digital signal generator **1040** may apply a constant value signal to the in-phase signal (I) and the quadrature signal (Q). The digital signal generator **1040** may apply sine and cosine wave signals **1070** to the in-phase signal (I) and the quadrature signal (Q), respectively. The N-bit digital waveform **830** may be adjusted to compensate for errors in at least one of the decoder **820**, the delta-sigma ($\Delta\Sigma$) modulator **840**, and the variable impedance **810**. The variable impedance **810** may include a filter for filtering noise generated by at least one of the decoder **820** and the delta-sigma ($\Delta\Sigma$) modulator **840**. The modulated signal may be an arbitrary signal. The wireless device **120** may be a RFID tag. The original signal may be received from a RFID reader **120**. The RFID reader **120** may be configured to correct for errors in at least one of the decoder **820**, the delta-sigma ($\Delta\Sigma$) modulator **840**, and the variable impedance **810**. The transmission apparatus **800** may further include a processor for controlling the transmission apparatus **800** and memory for storing the information **830**. The delta-sigma ($\Delta\Sigma$) modulator **840** may be one of a low-pass delta-sigma modulator and a band-pass delta-sigma modulator. The delta-sigma ($\Delta\Sigma$) modulator **840** may be a single bit delta-sigma modulator. And, the delta-sigma ($\Delta\Sigma$) modulator **840** may switch (S_1, S_2) the impedance value Z_i between at least two states (Z_1, Z_2).

The above embodiments may contribute to an improved method and apparatus for communications between wireless device **130** and reader **120** in backscattered and inductively coupled radio frequency identification systems and may provide one or more advantages. For example, the wireless devices **130** of the present invention are not limited in the nature of signals that they may backscatter or inductively couple to the reader **120**. In addition, the wireless devices **130** of the present invention allow for filtering of these signals. In addition, the delta-sigma ($\Delta\Sigma$) modulator **840** reduces the number of impedances that need to switch states in order to produce a signal. Furthermore, the delta-sigma ($\Delta\Sigma$) modulator **840** enables high levels of modulation with as few as only one impedance.

The embodiments of the invention described above are intended to be exemplary only. Those skilled in this art will understand that various modifications of detail may be made to these embodiments, all of which come within the scope of the invention.

What is claimed is:

1. A transmission apparatus for a wireless device, comprising:
 - an antenna for receiving an original signal and for backscattering a modulated signal containing information from the wireless device;
 - a variable impedance coupled to the antenna, the variable impedance having an impedance value;
 - a delta-sigma modulator coupled to the variable impedance for modulating the impedance value, and thereby a backscattering coefficient for the antenna, in accordance with the information to generate the modulated signal; and,
 - a decoder coupled to the delta-sigma modulator for generating the impedance value from the information.
2. The transmission apparatus of claim 1 wherein the variable impedance is coupled in series with the antenna.
3. The transmission apparatus of claim 1 wherein the wireless device is powered by energy from the original signal.
4. The transmission apparatus of claim 1 wherein the variable impedance includes an array of impedances and respective switches.
5. The transmission apparatus of claim 1 wherein the decoder includes a backscattering coefficient to impedance value decoder.

11

6. The transmission apparatus of claim 1 wherein the information is an N-bit digital waveform.

7. The transmission apparatus of claim 6 wherein the N-bit digital waveform is applied to the decoder and then to the delta-sigma modulator to produce a control signal for the variable impedance that is related to the N-bit digital waveform.

8. The transmission apparatus of claim 7 wherein a change in the impedance value backscatters the original signal to produce the modulated signal, the modulated signal being a frequency offset form of the N-bit digital waveform.

9. The transmission apparatus of claim 7 wherein the control signal for the variable impedance switches an array of impedances within the variable impedance which changes the impedance value and thereby changes characteristics of the backscattering coefficient of the antenna.

10. The transmission apparatus of claim 1 wherein the information is a complex modulation signal.

11. The transmission apparatus of claim 10 wherein the complex modulation signal is offset in frequency from the original signal.

12. The transmission apparatus of claim 10 wherein the complex modulation signal is one of a GMSK signal, a nPSK signal, a 8PSK signal, a nQAM signal, and an OFDM signal.

13. The transmission apparatus of claim 10 wherein the complex modulation signal is represented by $I+jQ$, where I is an in-phase component, Q is a quadrature component, and j is a square root of -1.

14. The transmission apparatus of claim 10 wherein the complex modulation signal alternates between an in-phase signal and a quadrature signal via a control signal.

15. The transmission apparatus of claim 14 wherein the variable impedance switches between backscattering coefficients that are 90 degrees offset from each other depending on whether the complex modulation signal is the in-phase signal or the quadrature signal.

16. The transmission apparatus of claim 14 wherein the control signal is a clock signal.

17. The transmission apparatus of claim 14 and further comprising a digital signal generator.

18. The transmission apparatus of claim 17 wherein the digital signal generator applies a constant value signal to the in-phase signal and the quadrature signal.

19. The transmission apparatus of claim 17 wherein the digital signal generator applies sine and cosine wave signals to the in-phase signal and the quadrature signal, respectively.

20. The transmission apparatus of claim 10 wherein the complex modulation signal is a sum of an in-phase signal and a quadrature signal.

21. The transmission apparatus of claim 20 and further comprising a digital signal generator.

22. The transmission apparatus of claim 21 wherein the digital signal generator applies a constant value signal to the in-phase signal and the quadrature signal.

23. The transmission apparatus of claim 21 wherein the digital signal generator applies sine and cosine wave signals to the in-phase signal and the quadrature signal, respectively.

24. The transmission apparatus of claim 6 wherein the N-bit digital waveform is adjusted to compensate for errors in at least one of the decoder, the delta-sigma modulator, and the variable impedance.

25. The transmission apparatus of claim 1 wherein the variable impedance includes a filter for filtering noise generated by at least one of the decoder and the delta-sigma modulator.

26. The transmission apparatus of claim 1 wherein the modulated signal is an arbitrary signal.

12

27. The transmission apparatus of claim 1 wherein the wireless device is a radio frequency identification ("RFID") tag.

28. The transmission apparatus of claim 1 wherein the original signal is received from a RFID reader.

29. The transmission apparatus of claim 28 wherein the RFID reader is configured to correct for errors in at least one of the decoder, the delta-sigma modulator, and the variable impedance.

30. The transmission apparatus of claim 1 and further comprising a processor for controlling the transmission apparatus and memory for storing the information.

31. A transmission apparatus for a wireless device, comprising:

an inductor for receiving an original signal and for transmitting by mutual inductance a modulated signal containing information from the wireless device;

a variable impedance coupled to the inductor, the variable impedance having an impedance value;

a delta-sigma modulator coupled to the variable impedance for modulating the impedance value, and thereby a value of the mutual inductance, in accordance with the information to generate the modulated signal; and,

a decoder coupled to the delta-sigma modulator for generating the impedance value from the information.

32. The transmission apparatus of claim 31 wherein the variable impedance is coupled in parallel with the inductor.

33. The transmission apparatus of claim 31 wherein the wireless device is powered by energy from the original signal.

34. The transmission apparatus of claim 31 wherein the variable impedance includes an array of impedances and respective switches.

35. The transmission apparatus of claim 31 wherein the information is an N-bit digital waveform.

36. The transmission apparatus of claim 35 wherein the N-bit digital waveform is applied to the decoder and then to the delta-sigma modulator to produce a control signal for the variable impedance that is related to the N-bit digital waveform.

37. The transmission apparatus of claim 36 wherein the modulated signal is a frequency offset form of the N-bit digital waveform.

38. The transmission apparatus of claim 36 wherein the control signal for the variable impedance switches an array of impedances within the variable impedance which changes the impedance value.

39. The transmission apparatus of claim 31 wherein the information is a complex modulation signal.

40. The transmission apparatus of claim 39 wherein the complex modulation signal is offset in frequency from the original signal.

41. The transmission apparatus of claim 39 wherein the complex modulation signal is one of a GMSK signal, a nPSK signal, a 8PSK signal, a nQAM signal, and an OFDM signal.

42. The transmission apparatus of claim 39 wherein the complex modulation signal is represented by $I+jQ$, where I is an in-phase component, Q is a quadrature component, and j is a square root of -1.

43. The transmission apparatus of claim 39 wherein the complex modulation signal alternates between an in-phase signal and a quadrature signal via a control signal.

44. The transmission apparatus of claim 43 wherein the variable impedance switches between impedance values that are 90 degrees offset from each other depending on whether the complex modulation signal is the in-phase signal or the quadrature signal.

13

45. The transmission apparatus of claim 43 wherein the control signal is a clock signal.

46. The transmission apparatus of claim 43 and further comprising a digital signal generator.

47. The transmission apparatus of claim 46 wherein the digital signal generator applies a constant value signal to the in-phase signal and the quadrature signal.

48. The transmission apparatus of claim 46 wherein the digital signal generator applies sine and cosine wave signals to the in-phase signal and the quadrature signal, respectively.

49. The transmission apparatus of claim 39 wherein the complex modulation signal is a sum of an in-phase signal and a quadrature signal.

50. The transmission apparatus of claim 49 and further comprising a digital signal generator.

51. The transmission apparatus of claim 50 wherein the digital signal generator applies a constant value signal to the in-phase signal and the quadrature signal.

52. The transmission apparatus of claim 50 wherein the digital signal generator applies sine and cosine wave signals to the in-phase signal and the quadrature signal, respectively.

53. The transmission apparatus of claim 35 wherein the N-bit digital waveform is adjusted to compensate for errors in at least one of the decoder, the delta-sigma modulator, and the variable impedance.

54. The transmission apparatus of claim 31 wherein the variable impedance includes a filter for filtering noise generated by at least one of the decoder and the delta-sigma modulator.

55. The transmission apparatus of claim 31 wherein the modulated signal is an arbitrary signal.

14

56. The transmission apparatus of claim 31 wherein the wireless device is a radio frequency identification ("RFID") tag.

57. The transmission apparatus of claim 31 wherein the original signal is received from a RFID reader.

58. The transmission apparatus of claim 57 wherein the RFID reader is configured to correct for errors in at least one of the decoder, the delta-sigma modulator, and the variable impedance.

59. The transmission apparatus of claim 31 and further comprising a processor for controlling the transmission apparatus and memory for storing the information.

60. The transmission apparatus of claim 1 wherein the delta-sigma modulator is one of a low-pass delta-sigma modulator and a band-pass delta-sigma modulator.

61. The transmission apparatus of claim 1 wherein the delta-sigma modulator is a single bit delta-sigma modulator.

62. The transmission apparatus of claim 1 wherein the delta-sigma modulator switches the impedance value between at least two states.

63. The transmission apparatus of claim 31 wherein the delta-sigma modulator is one of a low-pass delta-sigma modulator and a band-pass delta-sigma modulator.

64. The transmission apparatus of claim 31 wherein the delta-sigma modulator is a single bit delta-sigma modulator.

65. The transmission apparatus of claim 31 wherein the delta-sigma modulator switches the impedance value between at least two states.
